

Automotive Dealership Sales & Variance Analysis

Turning a flat headline revenue number into branch-level, financing-level findings a sales manager can act on.

BUSINESS QUESTION

Is dealership sales performance stable across the year, and are there branch-level or financing-type issues management should know about — beyond what the topline revenue figure shows?

DATA USED

A simulated automotive sales dataset covering 15 dealerships across Kenya: `sale_id`, `vehicle_id`, `customer_id`, `dealership_id`, `sale_date`, `sale_price_kes`, `discount_pct`, `financing_type`, `salesperson`, `customer_satisfaction` — roughly 2,500 transactions over 4 quarters, 5 financing types (Cash, Bank Loan, Dealer Financing, Lease, SACCO Loan).

Live PivotChart with Slicers (Quarters, Salesperson, Months)

APPROACH — WHAT I DID IN EXCEL

Built a PivotTable on the raw sales data with **Quarter** as the outer row field and **Dealership** then **Financing Type** nested beneath it, summarizing **Sum of sale_price_kes**. Added a PivotChart for the quarterly trend, then drilled into the dealership-level breakdown to compute each branch's variance against the fleet average and flag any single cell that broke from its own historical pattern.

KEY INSIGHTS

1. Flat aggregate hides real swings.

Quarterly revenue held within 4% of average (KES 2.29B–2.38B) — no seasonality — but two individual dealerships swung 36–45% quarter-to-quarter within that same stable total.

2. One branch is a consistent, structural underperformer.

DLR-0007 finished the year 23% below the 15-branch average — and was below average in every single quarter, not just one bad period, indicating a persistent branch issue rather than a one-off dip.

3. Two data points look like errors, not trends.

DLR-0013's SACCO Loan revenue and DLR-0008's Dealer Financing revenue each dropped over 85% in Q4 alone, with no matching drop elsewhere in that branch's numbers — flagged for data verification before being reported as a real trend.
